December 2008

Working Reports contain information on work in progress or pending completion.

The conclusions and viewpoints presented in the report are those of author(s) and do not necessarily coincide with those of Posiva.
ABSTRACT

The game statistics for the island of Olkiluoto were updated in March 2008. The estimates of game populations in Olkiluoto are based on interviews of local hunters, and other available statistical material. The collected data from the hunting season 2007-2008 were compared to earlier game animal studies performed in Olkiluoto. The following conclusions of changes in game populations are based on rough estimates primarily from interviews, not on accurate inventories of these animals.

The Elk population is slightly decreasing. The White-tailed Deer population is increasing remarkably. The changes in the Roe Deer population are not precisely known, but it seems that it is varying to some extent in different years. The populations of small mammalian predators (American Mink, Raccoon Dog and Red Fox) are strong in Olkiluoto. Compared to the previous years, they were hunted less in the hunting season 2007-2008. The more frequent sightings than earlier of Mountain Hare and European Hare seem to indicate that their populations are increasing, even though there are lots of predators (e.g. Sea Eagle and Eagle Owl) and a plenty of traffic in Olkiluoto. Other game animals (e.g. waterfowl) are currently hunted only minimally.

Keywords: Game statistics, hunting, Olkiluoto.

APPENDIX 2 : WEIGHTS OF THE SPECIES ..................................................... 19
1. INTRODUCTION AND STUDY AREA

The island of Olkiluoto (ca. 12 km²) is situated off the Finnish coast in the Bothnian Sea. The coast is characterised by shallow bays surrounded by small islands and skerries. The soil of this relatively flat island consists mainly of gravel, sand and fine-textured till. There are also some sedge and sphagnum peat soils, and exposed bedrock. The landscape at Olkiluoto is characterised by forests: pine, spruce, mixed coniferous, mixed deciduous/coniferous forests and deciduous forests. There are some small mires and near shore also meadows and shore scrubs. The whole local hydrogeochemical and biological system is affected by the postglacial land up-lift (6 mm/y) typical to the Finnish western coast.

There are two nuclear power plant units situated in Olkiluoto and a third one is under construction. Olkiluoto has also been selected as a location for final repository of spent nuclear fuel, and currently a test repository cave is under construction. These projects have taken over a large land area and traffic has increased a lot on the island.

This report was carried out by Satakunta Environmental Research Institute (University of Turku), where it was coordinated by Mikko Ojanen, and by Faunatica Oy, where coordinated by Marko Nieminen and Pekka Sundell. The work was ordered by Posiva Oy.
2. MATERIAL AND METHODS

A first estimate of game populations in Olkiluoto was conducted in 2002 (Kaapu 2003) and was based on interviews of local hunters and available statistical material. Next interviews were carried out in winter 2003-2004 (Ranta et al. 2005), updated by new interviews in January and March 2006 (Oja & Oja 2006). The most recent interviews were conducted in March 2007 (Oja & Oja 2007).

To update the game estimates, new interviews were carried out in March 2008. This current report is mainly based on interviews of hunters of a local hunting group (Olkiluodon metsästysseura) and inaccuracies can occur in the collected data. Only the data for Elk and White-tailed Deer are based on actual numbers of killed animals in the hunting season, others are based on oral statements and are more prone to error. The population sizes and their changes are based on observations and estimates by hunters in Olkiluoto, mainly by Kari Pipatti. Hunting statistics from the surrounding area and other corresponding data concerning game populations in Finland have been used to evaluate the estimates. Hunting statistics from the surrounding area were presented by Jari Toivonen, who is the chairman of the society of game preservation in SW Satakunta (Lounais-Satakunnan riistanhoitoyhdistys). The mean population densities are calculated from those statistics. Home range sizes are usually based on a combination of information from several sources, in which case references are not specified in “Habitat use” section. Observations and occurrence of suitable habitat for different species on Olkiluoto are presented elsewhere (see Jussila & Nieminen 2008).

List of scientific names of species mentioned in the report is shown in Appendix A with common names in English and Finnish. The average weights of game species are shown in Appendix B. Each weight represents a typical Finnish animal, heavier and lighter individuals do occur. The average weight is not a statistical mean but an estimated weight of both females and males. The literature used to construct species descriptions and Appendix B are listed in section 5 (References).
3. GAME ANIMALS IN OLKILUOTO

3.1. Mammals

3.1.1. Elk (*Alces alces*)

**Habitat use:** Elk typically inhabits boreal coniferous and mixed deciduous forests, and prefers continuously forested areas and relatively young forests. In spring and early summer elks are often seen on more open habitats such as mires. In the summer months they mainly inhabit areas with young deciduous trees around woodland glades and clearings, in the autumn they gather together in mature forests, in early winter along forest streams and rivers, and in the wintertime they prefer pine seedlings and young birch but also mature forests with lighter snow cover. Their home range is 5-10 km² on average. In Satakunta the mean density was 2.6-3.0 inds./1000 ha and in SW Satakunta 5.9 inds./1000 ha after the hunt in 2007.

**Main food source(s):** Elk consumes a variety of vegetation: leaves, needles, twigs and buds of trees (birch, aspen, willow, rowan) and shrubs (blueberry, lingonberry, heather), sprouts of cereals, grains and also some aquatic and terrestrial herbaceous plants. In winter it feeds on twigs and buds of trees and shrubs, bark and buds of pine and aspen, pine needles, juniper and lichens. Elk rarely feeds on spruce. Elks eat daily up to 50 kg in summertime and 10-20 kg in winter.

**Hunting in 2007:** Three adult Elks and four fawns were brought down in Olkiluoto (Table 1) (Toivonen 2008). One of the fawns was malformed or damaged and it was buried in the ground (Pipatti 2008). The estimated size of the Elk population after the hunting season was nine individuals. In 2002-2005 the estimated size of the Elk population had been 15-16 individuals (Fig. 1). It is possible that some Elks are moving to mainland from Olkiluoto. Likewise, there is some migration between Olkiluoto and the surrounding archipelago. Density after hunting in Olkiluoto in 2007 was ca. 7.5 inds./1000 ha.

Table 1. Numbers of hunted Elks and estimated population sizes before or after the hunting in different years.

3.1.2. White-tailed Deer (*Odocoileus virginianus*)

**Habitat use:** White-tailed Deer is a generalist and can use a wide variety of habitats. Mostly it is a forest animal depending on relatively small openings and edges. In the mornings and in the evenings White-tailed Deer can be seen grazing on the fields. Their home range is typically 10-100 ha. In Satakunta the mean density was 4.7 inds./1000 ha after the hunt in 2006-2007 and in SW Satakunta 9.3 inds./1000 ha after the hunt in 2007-2008.

**Main food source(s):** White-tailed Deer eats a variety of vegetation: grasses, herbaceous plants, leaves, needles, young shoots, acorns, mushrooms, sprouts of cereals, grains, root vegetables (sugar-beet), fruits and other cultivated plants. In winter, it feeds on shrubs (blueberry, lingonberry, heather), twigs, buds and bark of trees (aspen, willow, rowan) and also juniper, pine needles and lichens. It can also eat some fern and mosses, but consumes spruce rarely.

**Hunting in 2007-2008:** Altogether 14 White-tailed Deer were brought down (Table 2) (Pipatti 2008). The estimated size of the White-tailed Deer population was not recorded after the hunting season of 2007-2008. In 2004-2006 the estimated size of the White-tailed Deer population had been 10-25 individuals (Fig. 2). Density after hunting in Olkiluoto in 2007-2008 was ca. 16.7 inds./1000 ha.

3.1.3. Roe Deer (Capreolus capreolus)

Habitat use: Roe Deer lives mostly in woods, although it ventures regularly out to the grasslands, fields and sparse forests. Their home range in summertime is 50-100 ha on average.

Main food source(s): Roe Deer feeds mainly on grasses, herbaceous plants, leaves, young shoots, berries, mushrooms, sprouts of cereals and grains. It particularly likes very young, tender grass with a high moisture content, i.e. grass that has been watered by rain the previous day. In winter Roe Deer feeds on shrubs and lichens, twigs, buds and bark of trees and also some juniper and pine needles.

**Hunting in 2007-2008:** Probably two Roe Deer were brought down (Table 3) (Pipatti 2008). The exact number is difficult to determine because hunting of Roe Deer is now free and all hunters don’t notify the number they have killed. In 2004-2005 the estimated size of the Roe Deer population had been 5-20 (Fig. 3). Density after hunting in Olkiluoto in 2007-2008 was ca. 8.3 inds./1000 ha.

**Table 3. Numbers of hunted Roe Deer and estimated population sizes in different years.**

### 3.1.4. Red Fox (*Vulpes vulpes*)

**Habitat use:** Red Fox is a generalist and can adapt to a wide variety of habitats but is mainly found from forests, copses and field thickets, often in places with rock cavities or sandy ground. It can live in cultivated areas and near developments. In good habitats its home range is 5-12 km² and in poor habitats 12-50 km². In a case study in Virolahti their home range was 5.7 km² on average and density 0.44 inds./ km² (Kauhala ym. 2006). In Satakunta the mean density was 0.50-0.59 inds./km² in springtime 2007 (Kauhala 2007). The dispersal distances of young females were 21 km and of young males 29 km (Kauhala ym. 2006).
Main food source(s): Red Fox feeds mostly on various vertebrates, especially rodents (such as water voles, voles and mice), but also insects, molluscs, berries and fruits. They eat birds and eggs when available (Kauhala 2004, Kauhala ym. 1998). It can also catch bigger animals, like Mountain Hare, Brown Hare and even Roe Deer fawn. Sometimes it feeds on carrion and waste of foodstuff, such as surplus of butcheries and fisheries.

Hunting period: Whole year but female with fawns cannot be killed 1.5. – 31.7.

Hunting in 2007: Only a few Red Foxes were killed at Olkiluoto (Table 4) (Pipatti 2008). According to Kari Pipatti there is a strong population of Red Fox and the population has increased in Olkiluoto in the last few years. In Olkiluoto area Red Foxes move freely to and from mainland and there is also migration between Olkiluoto and the surrounding archipelago.

Table 4. Numbers of hunted Red Foxes in different years.

3.1.5. Raccoon Dog (Nyctereutes procyonoides)

Habitat use: Raccoon Dog lives in broadleaved and mixed woodlands intersected by streams and other water elements, and in scrubby and cultivated areas. Its home range is 2-10 km². In a case study in Virolahti their home range was 2.6 km² on average and density 0.77 inds./km² (Kauhala ym. 2006). In Satakunta the mean density was 0.60-0.69 inds./km² in springtime 2007 (Kauhala 2007). The dispersal distances of young females were 14 km and of young males 19 km (Kauhala ym. 2006).

Main food source(s): Raccoon Dog feeds on small mammals (also shrews) but also insects, larvae, earthworms, berries, fruits and grains. They eat birds and birds’ eggs when available and also aquatic organisms including fish (Kauhala 2004, Kauhala ym. 1998). Raccoon Dog consumes also reptiles and amphibians. It feeds on carrion and waste of foodstuff. It can also scavenge food from bins and gardens.

Hunting period: Whole year but female with fawns cannot be killed 1.5. – 31.7.

Hunting in 2007: No Raccoon Dogs were reported killed in Olkiluoto (Table 5) (Pipatti 2008). According to Kari Pipatti there is a strong and stable population of Raccoon Dogs in Olkiluoto. The number of catches does not necessary indicate the population size, because formerly the hunting of Raccoon Dog has been much more effective. In autumn Raccoon Dogs move around considerably, especially the young individuals.

Table 5. Numbers of hunted Raccoon Dogs in different years.

3.1.6. **European Badger** (*Meles meles*)

**Habitat use:** Badger lives in broadleaved and mixed woodlands and scrubby country intersected by fields and other kind of open areas. It can live in cultivated areas, near developments and even in urban area. In Southern Finland its home range is 3-5 km². In a case study in Virolahti their home range was 6.7 km² on average and density 0.26 inds./km² (Kauhala ym. 2006). In Satakunta the mean density was 0.20-0.29 inds./km² in springtime 2007 (Kauhala 2007).

**Main food source(s):** The diet of Badger consists of earthworms, insects, small mammals, reptiles, amphibians, eggs, young birds, berries, fruit, and other plant matter, depending on the season (Kauhala 2004, Kauhala ym. 1998). Badgers can also dig up the nests of wasps and bumblebees in order to eat their larvae. They also feed on carrion and waste of foodstuff and butchery. In urban areas some badgers can scavenge food from bins and gardens.

**Hunting period:** Whole year but female with fawns is not allowed to be killed 1.5. – 31.7.

**Hunting in 2007:** No Badgers were killed in Olkiluoto (Table 6) (Pipatti 2008). According to Kari Pipatti there is still one breeding Badger family on the island.

*Table 6. Numbers of hunted European Badgers in different years.*

3.1.7. **American Mink** (*Neovison vison*)

**Habitat use:** American Mink is found in the vicinity of rivers, streams, lakes and other water elements with thick herbaceous vegetation along the banks and it lives also by the seaside and archipelago. Home ranges of females are on average 8-20 ha and of males up to 800 ha.

**Main food source(s):** Feeds on small mammals, birds, eggs, amphibians, fish, aquatic invertebrates and also some insects.

**Hunting period:** Whole year but female with fawns is not allowed to be killed 1.5. – 31.7.

**Hunting in 2007:** Only a few American Minks were killed in Olkiluoto (Table 7) (Pipatti 2008). According to Kari Pipatti there is, however, a strong population of American Mink on the island and the population has increased in the latest years. American Mink finds a lot of food from the seashore, which is mainly open also in winter as the nuclear power plant heats up the sea water.

*Table 7. Numbers of hunted American Minks in different years.*

3.1.8. Pine Marten (*Martes martes*)

**Habitat use:** Pine Marten inhabits different kinds of forests, but mostly spruce forests. Recently it has adapted to more various habitats and nowadays it can live near developed areas. Home ranges of females are on average 9 km² and of males up to 18 km².

**Main food source(s):** Feeds on small rodents (mostly voles but also Red Squirrel), birds of different sizes, birds’ eggs, various insects, honey, molluses and berries, but sometimes it captures even larger prey such as hares. It can sometimes feed on carrion and waste of foodstuff and butchery.

**Hunting period:** 1.11.2007 – 31.3.2008.

**Hunting in 2007-2008:** No Pine Martens were killed in Olkiluoto (Table 8) (Pipatti 2008). According to Kari Pipatti there was one observation of Pine Marten on the island. It is possible that a pair or a solitary individual lives on the island.

*Table 8. Numbers of hunted Pine Martens in different years.*

3.1.9. Mountain Hare (*Lepus timidus*)

**Habitat use:** Mountain Hare is found in different habitats but it prefers forests and woodland glades, clearings, copses and field thickets. Its home range is from 2 to over 10 ha on average.

**Main food source(s):** The diet of Mountain Hare consists mainly of grasses, clovers, vetches, sprouts of oat, leaves (willow and aspen), shrubs (blackberry) but reed, sedge and herbs and berries are part of the nutrition. In winter Mountain Hare nibbles on the shoots and bark of young trees (birch, aspen, willow, rowan, juniper) and shrubs (blackberry).

**Hunting period:** 1.9.2007 – 29.2.2008.

**Hunting in 2007:** No Mountain Hares were killed in Olkiluoto (Table 9) (Pipatti 2008). According to Kari Pipatti there is a strong population of Mountain Hare and the population has increased in the latest years, even though there are lots of predators and traffic in Olkiluoto.

*Table 9. Numbers of hunted Mountain Hares in different years.*

3.1.10. Brown Hare (*Lepus europaeus*)

**Habitat use:** Brown Hare is found in cultivated areas and forest margins, and also sand dunes. It can live near developed areas and even in parks in urban area. Its home range is from 2 to over 20 ha on average.

**Main food source(s):** The diet consists mainly of grasses, clovers, vetches, yarrow, herbs and sprouts of cereals. In winter Brown Hare eats sprouts of cereals, grasses and hay, but also nibbles on the shoots and bark of young trees.

**Hunting period:** 1.9.2007 – 29.2.2008.

**Hunting in 2007-2008:** No Brown Hares were killed in Olkiluoto (Table 10) (Pipatti 2008). According to Kari Pipatti there is a stable population of European Hare and the population has obviously slightly increased in the latest years, even though there are lots of predators and traffic in Olkiluoto.

</table>

3.1.11. Muskrat (*Ondatra zibethicus*)

**Habitat use:** Muskrat is found on the banks of flowing and standing water bodies with luxuriant shore and aquatic vegetation. It also lives on the seaside if there is protective archipelago. Along 1 km of shore there can be ten muskrats during the summer and three during the winter.

**Main food source(s):** The diet consists of both plants and animals. Most popular plants are cattail, common club-rush, sedges, water horsetail and sometimes common reed. In wintertime mussels are important food for Muskrat and it feeds also on crayfish and dead fishes, but it cannot catch living fish.

**Hunting period:** 1.10.2007 – 19.5.2008.

**Hunting in 2007-2008:** No Muskrats were killed in Olkiluoto. There is probably no Muskrat population in Olkiluoto anymore.

3.1.12. Red Squirrel (*Sciurus vulgaris*)

**Habitat use:** Red Squirrel is found on woodlands, parks and gardens, often in the immediate vicinity of humans. Its home range is 2-5 ha on average.
Main food source(s): Red Squirrel eats mostly the seeds of coniferous (spruce, pine) trees, neatly stripping conifer cones to get at the seeds within. Mushrooms, berries, young shoots, buds, flowers, fruits and nuts are also parts of the diet. Often Red Squirrel removes the bark of trees to access sap. Occasionally Red Squirrel eats animal food like birds' eggs, nestlings, insects and larvae.

Hunting in 2007-2008: No Red Squirrels were killed, though there is still a stable population of Red Squirrel in Olkiluoto.

3.2. Birds

3.2.1. Mallard (Anas platyrhynchos)

Habitat use: Mallard is found near all types of wetland habitats, except the least productive and most barren waters. It also lives on seashore.

Population density: There are on average 3.5 nesting pairs of Mallards per km² on lakes and river estuaries in Satakunta. Mallard is quite abundant also at seashore and in the inner archipelago.

Main food source(s): Feeds on insects and larvae, other (mainly aquatic) invertebrates, seeds, aquatic vegetation and grain.

Hunting in 2007: No Mallards were caught, though there is a stable population of Mallard in Olkiluoto.

3.2.2. Teal (Anas crecca)

Habitat use: Teal favours freshwater pools, lakes and streams with luxuriant shore vegetation, preferring shallower waters and smaller ponds and pools in breeding season. It also lives on seashore.

Population density: There are on average 2.9 nesting pairs of Teals per km² on lakes in Satakunta. However, Teal is much rarer at bays of the Baltic than on the mainland.

Main food source(s): Feeds on insects and larvae, other aquatic invertebrates like gastropods, and seeds and aquatic vegetation.

**Hunting in 2007:** No Teals were caught in Olkiluoto. It is not known if there are any breeding pairs of Teal in Olkiluoto.

### 3.2.3. Hazel Grouse (*Bonasa bonasia*)

**Habitat use:** Hazel Grouse inhabits different kinds of mixed forests, but favours dense spruce forests with some deciduous trees. It prefers glens of streams and coastal areas of lakes and the sea, where alder is abundant.

**Population density:** There are on average 2 nesting pairs of Hazel Grouse per km$^2$ in spruce forests and 4 pairs in mixed forests in southern Finland.

**Main food source(s):** Hazel Grouse feeds mostly on the ground, feeding mainly on plant food like leaves and shoots of herbaceous plants and shrubs, seeds and berries, supplemented by insects when breeding. Fledglings of Hazel Grouse eat insects. In winter Hazel Grouse eats buds and catkins of deciduous trees (alder, birch).

**Hunting period:** 10.9. – 31.10.2007.

**Hunting in 2007:** No Hazel Grouses were caught, though there is a stable population of Hazel grouse in Olkiluoto.

### 3.2.4. Black Grouse (*Tetrao tetrix*)

**Habitat use:** Black Grouse inhabits bright boreal forests near moorland, bog areas and fields. It also lives in the archipelago. In winter Black Grouses gather to birch forests, where they find enough food.

**Population density:** There are on average 0.8 nesting pairs of Black Grouse per km$^2$ in south-western Finland.

**Main food source(s):** Black Grouse feeds mainly on plants like leaves, shoots and buds of shrubs, seed, berries and herbaceous plants. It also eats sprouts of cereals and grains on the fields. Fledglings of Black grouse eat insects, spiders and other small animals. In winter Black Grouse eats buds and catkins of birch, aments of alder and pine needles.

**Hunting period:** 10.9. – 31.10.2007.

**Hunting in 2007:** No Black Grouses were caught, though there apparently is a small population of Black Grouse in Olkiluoto.
3.2.5. **Woodcock (Scolopax rusticola)**

**Habitat use:** Woodcock inhabits moist boreal forests, luxuriant mixed forests and broadleaved groves.

**Population density:** There are on average 0.9 nesting pairs of Woodcock per km$^2$ in south-western Finland.

**Main food source(s):** Woodcock mainly eats earthworms, larvae, snails, insects and other invertebrates, but also plant material like seed and berries.

**Hunting in 2007:** No Woodcocks were caught, though there apparently is a stable population of Woodcock in Olkiluoto.

---

3.2.6. **Hooded Crow (Corvus corone)**

**Habitat use:** Hooded Crow lives in forests, open countryside, parks and gardens, often in the immediate vicinity of humans. It also lives in the archipelago.

**Population density:** There are on average 1.9 nesting pairs of Hooded Crow per km$^2$ in south-western Finland.

**Main food source(s):** The Hooded Crow is omnivorous and a regular scavenger. It feeds on insects, earthworms, fish, molluscs, grains, seeds and fruits. Occasionally it eats eggs and nestlings from bird nests. In coastal areas it drops molluscs and crabs to break them. Hooded Crow also eats carrion, debris, and wastes of foodstuff and slaughterhouses, etc.

**Hunting period:** 1.8.2007 – 9.3.2008.

**Hunting in 2007:** No Hooded Crows were caught, though there apparently is a strong and stable population of Hooded Crow in Olkiluoto.
4. DISCUSSION

This study deals with game statistics for the island of Olkiluoto and it is based on interviews of local hunters and numbers of kills of game animals. The population sizes and their variations are based on observations and estimates made by hunters in Olkiluoto. The descriptions of habitat use and food sources are based on public literature and scientific articles. Knowledge of animals behavior in SW Finland has also been used in these descriptions.

The population of Elk is slightly decreasing like in other areas in SW Satakunta (hunting area of Lounais-Suomen riistanhoitoyhdistys) and in S Finland. This is a result from efficient hunting in several years and also from some natural reasons (Leppäniemi & Halla 2006, Svensberg & Vikberg 2008a). The population of White-tailed Deer is increasing remarkably like in other areas in SW Satakunta and SW Finland (Svensberg & Vikberg 2008b). This results from warm winter conditions and low hunting pressure during the latest years. The changes in the population of Roe Deer are not exactly known, but it seems that it is varying to some extent in different years. The number of kills of Roe Deer has been decreasing in SW Satakunta in last three years and in Finland it has been stable for the latest five years (Svensberg & Vikberg 2008b).

The populations of small mammal predators (American Mink, Raccoon Dog and Red Fox) are at a very high level in Olkiluoto. These species were hunted less in the hunting season 2007-2008 compared with previous years (Pipatti 2008). One reason for this is that hunters have previously (years 2001 and 2002) been awarded from catching these animals (Ermala 2008, Pipatti 2008).

The more frequent sightings of the Mountain Hare and European Hare seem to indicate that their populations are increasing even though there are a lot of predators (Eagle and Eagle Owl) and traffic in Olkiluoto (Pipatti 2008). Other game animals like waterfowls are currently hunted only minimally.
